Summer School in Economics and Econometrics University of Crete July 23-27, 2012

Bruce Hansen (University of Wisconsin)

Structural Breaks

July 23-27, 2012 1 / 99

Organization

- Detection of Breaks
- Estimating Breaks
- Forecasting after Breaks

< A > < 3

Types of Breaks

- Breaks in Mean
- Breaks in Variance
- Breaks in Relationships
- Single Breaks
- Multiple Breaks
- Continuous Breaks

Example

• Simple AR(1) with mean and variance breaks

$$y_t = \rho y_{t-1} + \mu_t + e_t$$

$$e_t \sim N(0, \sigma_t^2)$$

$$Ey_t = \frac{\mu_t}{1-\rho}$$
$$var(y_t) = \frac{\sigma_t^2}{1-\rho^2}$$

- μ_t and/or σ_t^2 may be constant or may have a break at some point in the sample
- Sample size *n*
- Questions: Can you guess:
 - Is there a structural break?
 - If so, when?
 - Is the shift in the mean or variance? How large do you guess?

Model C: Data

July 23-27, 2012 6 / 99

э.

3

・ロト ・回ト ・ヨト

Terminology

- Sample Period: t = 1, ..., n
- Breakdate: T_1
 - Date of change
- Breakdate fraction: $au_1 = T_1/n$
- Pre-Break Sample: $t = 1, ..., T_1$
 - T₁ observations
- Post-Break Sample: $t = T_1 + 1, ..., n$
 - $n T_1$ observations

3

< 回 ト < 三 ト < 三 ト

Structural Break Model

• Full structural break

$$\begin{aligned} y_t &= \beta_1' \mathbf{x}_t + e_t, \qquad t \leq T_1 \\ y_t &= \beta_2' \mathbf{x}_t + e_t, \qquad t > T_1 \end{aligned}$$

or

$$y_t = \boldsymbol{\beta}_1' \mathbf{x}_t \mathbf{1} \left(t \leq T_1 \right) + \boldsymbol{\beta}_2' \mathbf{x}_t \mathbf{1} \left(t > T_1 \right) + \boldsymbol{e}_t$$

• Partial structural break

$$y_t = oldsymbol{eta}_0' oldsymbol{z}_t + oldsymbol{eta}_1' oldsymbol{x}_t \mathbf{1} \left(t \leq T_1
ight) + oldsymbol{eta}_2' oldsymbol{x}_t \mathbf{1} \left(t > T_1
ight) + oldsymbol{e}_t$$

Variance Break Model

$$y_t = \boldsymbol{\beta}' \mathbf{x}_t + \boldsymbol{e}_t,$$

$$\operatorname{var}(\boldsymbol{e}_t) = \sigma_1^2, \quad t \le T_1$$

$$\operatorname{var}(\boldsymbol{e}_t) = \sigma_2^2, \quad t > T_1$$

- Breaks do not necessarily affect point forecasts
- Affects forecast variances, intervals, fan charts, densities

< 🗇 🕨 < 🖃 🕨

Detection of Breaks

3

<ロ> (日) (日) (日) (日) (日)

Testing for a Break

Classic Test (Chow)

- Assume T_1 is known
- Test $H_0: oldsymbol{eta}_1 = oldsymbol{eta}_2$
- Use classic linear hypothesis test (F, Wald, LM, LR)
- Least-Squares

$$y_t = \widehat{\boldsymbol{\beta}}_0' \mathbf{z}_t + \widehat{\boldsymbol{\beta}}_1' \mathbf{x}_t \mathbf{1} (t \leq T_1) + \widehat{\boldsymbol{\beta}}_2' \mathbf{x}_t \mathbf{1} (t > T_1) + \hat{\mathbf{e}}_t$$

3

→

< A > < 3

Full Break Model

$$\begin{array}{rcl} Y_1 &=& X_1 \boldsymbol{\beta}_1 + \boldsymbol{e}_1 \\ Y_2 &=& X_1 \boldsymbol{\beta}_2 + \boldsymbol{e}_2 \end{array}$$

$$\widehat{oldsymbol{eta}}_1 = (X_1'X_1)^{-1}(X_1'Y_1) \ \widehat{oldsymbol{eta}}_2 = (X_2'X_2)^{-1}(X_2'Y_2)$$

$$\hat{e}_1 = Y_1 - X_1 \widehat{\beta}_1 \hat{e}_2 = Y_2 - X_2 \widehat{\beta}_2$$

$$SSE(T_1) = \hat{e}'_1 \hat{e}_1 + \hat{e}'_2 \hat{e}_2 \\ \hat{\sigma}^2(T_1) = \frac{1}{n-m} \left(\hat{e}'_1 \hat{e}_1 + \hat{e}'_2 \hat{e}_2 \right)$$

3

・ロト ・聞ト ・ヨト ・ヨト

F Test Statistic

• F test

$$F(T_1) = \frac{(SSE - SSE(T_1)) / k}{SSE(T_1)(n-m)}$$

where $k = \dim(\beta_1)$, m =all parameters,

$$\begin{array}{rcl} SSE & = & \tilde{e}'\tilde{e} \\ \tilde{\sigma}^2 & = & \frac{1}{n-k}\left(\tilde{e}'\tilde{e}\right) \\ \tilde{e} & = & Y-X\widetilde{\beta} \end{array}$$

(full sample estimate)

> F test assumes homoskedasticity, better to use Wald test

3

(日) (同) (三) (三)

Wald Test Statistic

$$W(T_1) = n\left(\widehat{\beta}_1 - \widehat{\beta}_2\right)' \left(\widehat{V}_1 \frac{n}{T_1} + \widehat{V}_2 \frac{n}{n - T_1}\right)^{-1} \left(\widehat{\beta}_1 - \widehat{\beta}_2\right)$$

where \hat{V}_1 and \hat{V}_2 are standard asymptotic variance estimators for $\hat{\beta}_1$ and $\hat{\beta}_2$ (on the split samples:

$$\begin{array}{rcl} \widehat{V}_1 & = & \widehat{Q}_1^{-1}\widehat{\Omega}_1\widehat{Q}_1^{-1} \\ \widehat{V}_2 & = & \widehat{Q}_2^{-1}\widehat{\Omega}_2\widehat{Q}_2^{-1} \end{array}$$

$$\widehat{Q}_1 = \frac{1}{T_1} X_1' X_1$$
$$\widehat{Q}_2 = \frac{1}{n - T_1} X_2' X_2$$

HAC variance options

• For iid *e*_t

$$egin{array}{rcl} \widehat{\Omega}_1 &=& ilde{\sigma}^2 \widehat{Q}_1 \ \widehat{\Omega}_2 &=& ilde{\sigma}^2 \widehat{Q}_2 \end{array}$$

• For homoskedastic (within regiome

$$\hat{\sigma}_1^2 = \frac{1}{T_1 - k} \left(\hat{\mathbf{e}}_1' \hat{\mathbf{e}}_1 \right)$$
$$\hat{\sigma}_2^2 = \frac{1}{n - T_1 - k} \left(\hat{\mathbf{e}}_2' \hat{\mathbf{e}}_2 \right)$$

• For serially uncorrelated but possibly heteroskedastic

$$\widehat{\Omega}_1 = \frac{1}{T_1 - k} \sum_{t=1}^{T_1} \mathbf{x}_t \mathbf{x}'_t \widehat{\mathbf{e}}_t^2$$
$$\widehat{\Omega}_2 = \frac{1}{n - T_1 - k} \sum_{t=T_1+1}^n \mathbf{x}_t \mathbf{x}'_t \widehat{\mathbf{e}}_t^2$$

• For serially correlated (e.g. h > 1)

$$\begin{split} \widehat{\Omega}_{1} &= \frac{1}{T_{1}-k} \sum_{t=1}^{T_{1}} \mathbf{x}_{t} \mathbf{x}_{t}' \widehat{\mathbf{e}}_{t}^{2} \\ &+ \frac{1}{T_{1}-k} \sum_{j=0}^{h-1} \sum_{t=1}^{T_{1}-j} \left(\mathbf{x}_{t} \mathbf{x}_{t+j}' \widehat{\mathbf{e}}_{t} \widehat{\mathbf{e}}_{t+j} + \mathbf{x}_{t+j} \mathbf{x}_{t}' \widehat{\mathbf{e}}_{t+j} \widehat{\mathbf{e}}_{t} \right) \\ \widehat{\Omega}_{2} &= \frac{1}{n-T_{1}-k} \sum_{t=T_{1}+1}^{n} \mathbf{x}_{t} \mathbf{x}_{t}' \widehat{\mathbf{e}}_{t}^{2} \\ &+ \frac{1}{n-T_{1}-k} \sum_{j=0}^{h-1} \sum_{t=T_{1}+1}^{n-j} \left(\mathbf{x}_{t} \mathbf{x}_{t+j}' \widehat{\mathbf{e}}_{t} \widehat{\mathbf{e}}_{t+j} + \mathbf{x}_{t+j} \mathbf{x}_{t}' \widehat{\mathbf{e}}_{t+j} \widehat{\mathbf{e}}_{t} \right) \end{split}$$

3

イロト イヨト イヨト イヨト

Classic Theory

• Under H_0 , if the number of observations pre- and post-break are large, then

$$F(T_1) \to_d \frac{\chi_k^2}{k}$$

under homoskedasticity, and in general

$$W(T_1) \rightarrow_d \chi_k^2$$

- We can reject H_0 in favor of H_1 if the test exceeds the critical value
 - Thus "find a break" if the test rejects

Modern Approach

- Break dates are unknown
- Sup tests (Andrews, 1993)

SupF =
$$\sup_{T_1} F(T_1)$$

SupW = $\sup_{T_1} W(T_1)$

- The sup is taken over all break dates T_1 in the region $[t_1, t_2]$ where $t_1 >> 1$ and $t_2 << n$
 - The region [t₁, t₂] are candidate breakdates. If the proposed break is too near the beginning or end of sample, the estimates and tests will be misleading
 - Recommended rule $t_1 = [.15n]$, $t_2 = [.85n]$
- Numerically, calculate SupW using a loop

Example

- US GDP example presented yesterday
- Quarterly data 1960:2011
- *k* = 7

→ Ξ →

GDP: Test for Regression Shift

July 23-27, 2012 20 / 99

- 2

▲□▶ ▲圖▶ ▲厘▶ ▲厘▶

Evidence for Structural Break?

- SupW=27
- Is this significant?

< 🗗 🕨

Theorem (Andrews)

- Under H_0 , if the regressors \mathbf{x}_t are strictly stationary, then
 - SupF, SupW, etc, converge to non-standard asymptotic distributions which depend on
 - \star k (the number of parameters tested for constancy

$$\star$$
 $\pi_1 = t_1/r_1$

$$\star$$
 $\pi_2 = t_2/n$

- ★ Only depend on π_1 and π_2 through $\lambda = \pi_2(1-\pi_1)/(\pi_1(1-\pi_2))$
- Critical values in Andrews (2003, Econometrica, pp 395-397)
- p-value approximation function in Hansen (1997 JBES, pp 60-67)
- Critical values much larger than chi-square

Evidence for Structural Break?

- SupW=27
- *k* = 7
- 1% asymptotic critical value = 26.72
- Asymptotic p-value=0.008

___ ▶

Non-Constancy in Marginal or Conditional?

The model is

$$y_t = oldsymbol{eta}_0' oldsymbol{z}_t + oldsymbol{eta}_1' oldsymbol{x}_t \mathbf{1} \left(t \leq T_1
ight) + oldsymbol{eta}_2' oldsymbol{x}_t \mathbf{1} \left(t > T_1
ight) + oldsymbol{e}_t$$

- The goal is to check for non-constancy in the conditional relationship (in the coefficients β) while being agnostic about the marginal (the distribution of the regressors x_t)
- Andrews assume that **x**_t are strictly stationary, which excludes structural change in the regressors
- In Hansen (2000, JoE) I show that this assumption is binding
 - If x_t has a structural break in its mean or variance, the asymptotic distribution of the SupW test changes
 - This can distort inference (a large test may be due to instability in x_t, not regression instability)
- There is a simple solution: Fixed Regressor Bootstrap
 - Requires h = 1 (no serial correlation)

- 3

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

Fixed Regressor Bootstrap

- Similar to a bootstrap, a method to simulate the asymptotic null distribution
- Fix $(z_t, x_t, \hat{e}_t), t = 1, ..., n$
- Let y_t^* be iid $N(0, \hat{e}_t^2)$, t = 1, ..., n
- Estimate the regression

$$y_t^* = \widehat{\boldsymbol{\beta}}_0^{*\prime} \mathbf{z}_t + \widehat{\boldsymbol{\beta}}_1^{*\prime} \mathbf{x}_t \mathbf{1} (t \le T_1) + \widehat{\boldsymbol{\beta}}_2^{*\prime} \mathbf{x}_t \mathbf{1} (t > T_1) + \widehat{\mathbf{e}}_t^*$$

Form the Wald, SupW statistics on this simulated data

$$W^{*}(T_{1}) = n \left(\widehat{\beta}_{1}^{*}(T_{1}) - \widehat{\beta}_{2}^{*}(T_{1}) \right)' \left(\widehat{V}_{1}^{*}(T_{1}) \frac{n}{T_{1}} + \widehat{V}_{2}^{*}(T_{1}) \frac{n}{n - T_{1}} \right)^{-1} \\ \left(\widehat{\beta}_{1}^{*}(T_{1}) - \widehat{\beta}_{2}^{*}(T_{1}) \right)$$

$$\mathsf{SupW}^* = \sup_{\mathcal{T}_1} \mathcal{W}^*(\mathcal{T}_1)$$

- Repeat this $B \ge 1000$ times.
- Let SupW^{*}_b denote the b'th value
- Fixed Regressor bootstrap p-value

$$p = rac{1}{B}\sum_{b=1}^{N} \mathbb{1}\left(\mathsf{SupW}_{b}^{*} \geq \mathsf{SupW}^{*}
ight)$$

- Fixed Regressor bootstrap critical values are quantiles of empirical distribution of SupW^{*}_b
- Important restriction: Requires serially uncorrelated errors (h = 1)

GDP: Test for Regression Shift

July 23-27, 2012 27 / 99

- 2

▲□▶ ▲圖▶ ▲厘▶ ▲厘▶

Evidence for Structural Break?

- SupW=27
- Asymptotic p-value=0.008
- Fixed regressor bootstrap p-value=0.106
- Bootstrap eliminates significance!

Recommendation

- In small samples, the SupW test highly over-rejects
- The Fixed Regressor Bootstrap (h = 1) greatly reduces this problem
- Furthermore, it makes the test robust to structural change in the marginal distribution
- For h > 1, tests not well investigated

Testing for Breaks in the Variance

$$y_t = \boldsymbol{\beta}' \mathbf{x}_t + e_t$$
,

$$\begin{aligned} \operatorname{var}\left(e_{t}\right) &= \sigma_{1}^{2}, \quad t \leq T_{1} \\ \operatorname{var}\left(e_{t}\right) &= \sigma_{2}^{2}, \quad t > T_{1} \end{aligned}$$

- Since $var(e_t) = Ee_t^2$, this is the same as a test for a break in a regression of e_t^2 on a constant
- Estimate constant-parameter model

$$y_t = \widehat{oldsymbol{eta}}' \mathbf{x}_t + \hat{e}_t$$

- Obtain squared residuals \hat{e}_t^2
- Apply Andrews SupW test to a regression of \hat{e}_t^2 on a constant
- k = 1 critical values

GDP Example: Break in Variance?

• Apply test to squared OLS residuals

< 67 ▶

GDP: Test for Variance Shift

Break in Variance?

- SupW=15.96
- k = 1
- 1% asymptotic critical value =12.16
- Asymptotic p-value=0.002
- Fixed regressor bootstrap p-value=0.000
- Strong rejection of constancy in variance
 - Great moderation

End-of-Sample Breaks

3

<ロ> (日) (日) (日) (日) (日)

End-of-Sample Breaks

- The SupW tests are powerful against structural changes which occur in the interior of the sample
- $T_1 \in [.15n, .85n]$
- Have low power against breaks at the end of the sample
- Yet for forecasting, this is a critical period
- Classic Chow test allows for breaks at end of sample
 - But requires finite sample normality
- New end-of-sample instability test by Andrews (Econometrica, 2003)
End-of-Sample Test

Write model as

$$Y_1 = X_1 \boldsymbol{\beta}_1 + \boldsymbol{e}_1$$

$$Y_2 = X_1 \boldsymbol{\beta}_{2t} + \boldsymbol{e}_2$$

where Y_1 is $n \times 1$, Y_2 is $m \times 1$ and X has k regressors

- *m* is known but small
- Test is for non-constancy in β_{2t}
- Let $\widehat{m{eta}}$ be full sample (n+m) LS estimate, $\hat{e} = Y X \widehat{m{eta}}$ full-sample residuals
- Partition $\hat{e} = (\hat{e}_1, \hat{e}_2)$
- Test depends on $\Sigma = E(e_2e'_2)$
- First take case $\Sigma = I_m \sigma^2$

• If $m \ge d$ $S = \hat{e}_2' X_2 (X_2' X_2)^{-1} X_2' \hat{e}_2$ • If m < d

$$P = \hat{e}_2' X_2 X_2' \hat{e}_2$$

- If *m* is large we could use a chi-square approximation
- But when m is small we cannot

3

< //2 → < 三

Andrews suggests a subsampling-type p-value

$$p = \frac{1}{n-m+1} \sum_{j=1}^{n-m+1} \mathbb{1} \left(S \le S_j \right)$$

$$\begin{array}{rcl} S_{j} & = & \hat{e}_{j}'X_{j}\left(X_{j}'X_{j}\right)^{-1}X_{j}'\hat{e}_{j} \\ X_{j} & = & \{\mathbf{x}_{t}:t=j,...,j+m-1\} \\ Y_{j} & = & \{y_{t}:t=j,...,j+m-1\} \\ \hat{e}_{j} & = & Y_{j}-X_{j}\widehat{\boldsymbol{\beta}}_{(j)} \end{array}$$

and $\widehat{m{eta}}_{(j)}$ is least-squares using all observations **except** for t=j,...,j+[m/2]

- Similar for P test
- You can reject end-of-sample stability if p is small (less than 0.05)

イロト 不得下 イヨト イヨト 二日

Weighted Tests

Andrews suggested improved power by exploiting correlation in e2

$$S = \hat{\mathsf{e}}_2' \hat{\Sigma}^{-1} X_2 \left(X_2' \hat{\Sigma}^{-1} X_2
ight)^{-1} X_2' \hat{\Sigma}^{-1} \hat{\mathsf{e}}_2$$

where

$$\hat{\Sigma} = rac{1}{n+1}\sum_{j=1}^{n+1} \left(Y_j - X_j\widehat{oldsymbol{eta}}
ight) \left(Y_j - X_j\widehat{oldsymbol{eta}}
ight)'$$

• The subsample calculations are the same as before except that

$$S_j = \hat{e}_j^\prime \hat{\Sigma}^{-1} X_j \left(X_j^\prime \hat{\Sigma}^{-1} X_j
ight)^{-1} X_j^\prime \hat{\Sigma}^{-1} \hat{e}_j$$

3

18 A.

< + **-□** < - < <

Example: End-of-Sample Instability in GDP Forecasting?

- *m* = 12 (last 3 years)
- S statistics (p-values)

	Unweighted	Weighted		
h=1	.20	.21		
h = 2	.08	.36		
h = 3	.02	.29		
<i>h</i> = 4	.18	.27		
h = 5	.95	.94		
h = 6	.91	.83		
h = 7	.86	.70		
h = 8	.78	.86		

• Evidence does not suggest end-of-sample instability

Breakdate Estimation

3

Breakdate Estimation

• The model is a regression

$$y_t = \boldsymbol{\beta}_0' \mathbf{z}_t + \boldsymbol{\beta}_1' \mathbf{x}_t \mathbf{1} \left(t \leq T_1 \right) + \boldsymbol{\beta}_2' \mathbf{x}_t \mathbf{1} \left(t > T_1 \right) + \mathbf{e}_t$$

- Thus a natural estimator is least squares
- The SSE function is

$$S(\boldsymbol{\beta}, T_1) = \frac{1}{n} \sum_{t=1}^{n} \left(y_t - \boldsymbol{\beta}_0' \mathbf{z}_t - \boldsymbol{\beta}_1' \mathbf{x}_t \mathbf{1} \left(t \le T_1 \right) - \boldsymbol{\beta}_2' \mathbf{x}_t \mathbf{1} \left(t > T_1 \right) \right)^2$$
$$(\widehat{\boldsymbol{\beta}}, \widehat{T}_1) = \operatorname{argmin} S(\boldsymbol{\beta}, T_1)$$

- The function is quadratic in β , nonlinear in T_1
 - Convenient solution is concentration

Least-Squares Algorithm

$$(\widehat{\boldsymbol{\beta}}, \widehat{\boldsymbol{T}}_{1}) = \operatorname*{argmin}_{\boldsymbol{\beta}, \boldsymbol{\tau}_{1}} S(\boldsymbol{\beta}, \boldsymbol{T}_{1})$$

=
$$\operatorname{argmin}_{\boldsymbol{\tau}_{1}} \min_{\boldsymbol{\beta}} S(\boldsymbol{\beta}, \boldsymbol{T}_{1})$$

=
$$\operatorname{argmin}_{\boldsymbol{\tau}_{1}} S(\boldsymbol{T}_{1})$$

where

$$S(T_1) = \min_{\beta} S(\beta, T_1)$$
$$= \frac{1}{n} \sum_{t=1}^{n} \hat{e}_t (T_1)^2$$

and $\hat{e}_t(T_1)$ are the OLS residuals from

$$y_t = \widehat{\boldsymbol{\beta}}_0' \mathbf{z}_t + \widehat{\boldsymbol{\beta}}_1' \mathbf{x}_t \mathbf{1} (t \le T_1) + \widehat{\boldsymbol{\beta}}_2' \mathbf{x}_t \mathbf{1} (t > T_1) + \hat{\mathbf{e}}_t(T_1)$$

with T_1 fixed.

3

▲ @ > < ∃</p>

Least-Squares Estimator

$$\widehat{T}_1 = \operatorname*{argmin}_{T_1} S(T_1)$$

- For each $T_1 \in [t_1, t_2]$, estimate structural break regression, calculate residuals and SSE $S(T_1)$
- Find T_1 which minimizes $S(T_1)$
- Even if *n* is large, this is typically a quick calculation.
- Plots of $S(T_1)$ against T_1 are useful
- The sharper the "peak", then better T_1 is identified

Example: Breakdate Estimation in GDP

- Plot SSE as function of breakdate
- Break Date Estimate is lowest point of graph

GDP: SSE for Regression Break Date

July 23-27, 2012 46 / 99

Break Date Estimate

- \widehat{T}_1 (minimum of $SSE(T_1) = 1980:4$ (82nd observation)
- Minimum not well defined
- Consistent with weak break or no break

Example: Breakdate Estimation for GDP Variance

• Plot SSE as function of breakdate

47 ▶

<ロ> (日) (日) (日) (日) (日)

Break Date Estimate for Variacne

- \hat{T}_1 (minimum of $SSE(T_1) = 1983:4$ (93rd observation)
- Well defined minimum
- Sharp V shape
- Consistent with strong single break

Distribution Theory and Confidence Intervals

3

Distribution of Break-Date Estimator

- Bai (Review of Economics and Statistics, 1997)
- Define

$$Q = E(\mathbf{x}_t \mathbf{x}_t')$$

$$\Omega = E(\mathbf{x}_t \mathbf{x}_t' \mathbf{e}_t^2)$$

$$\delta = \beta_2 - \beta_1$$

3

3 ×

Theorem

[If $\delta \to 0$, and the distribution of (\mathbf{x}_t, e_t) does not change at T_1 , then]

$$\frac{\left(\delta'Q\delta\right)^2}{\delta'\Omega\delta}\left(\widehat{T}_1-T_1\right)\to_d \zeta = \operatorname*{argmax}_{s}\left[W(s)-\frac{|s|}{2}\right]$$

where W(s) is a double-sided Brownian motion. The distribution of ζ for $x \ge 0$ is

$$G(x) = 1 + \sqrt{\frac{x}{2\pi}} \exp\left(-\frac{x}{8}\right) - \frac{x+5}{2}\Phi\left(-\frac{\sqrt{x}}{2}\right) + \frac{3e^x}{2}\Phi\left(-\frac{3\sqrt{x}}{2}\right)$$

and G(x)=1-G(-x).If the errors are iid, then $\Omega_1=\mathcal{Q}_1\sigma_1^2$ and

$$\frac{\delta' Q_1 \delta}{\sigma_1^2} \left(\widehat{T}_1 - T_1 \right) \to_d \zeta$$

イロト 不得下 イヨト イヨト 二日

Critical Values (Bai Method)

Critical values for ζ can be solved by inverting G(x):

Coverage	С
80%	4.7
90%	7.7
95%	11.0

< 4 ∰ > <

Confidence Intervals for Break Date (Bai Method)

• Point Estimate \widehat{T}_1

• Theorem:
$$\widehat{T}_1 \sim T_1 + rac{\delta'\Omega\delta}{\left(\delta'Q\delta
ight)^2} \zeta$$

• Confidence interval is then

$$\widehat{\mathcal{T}}_{1}\pmrac{\widehat{\delta}'\widehat{\Omega}\widehat{\delta}}{\left(\widehat{\delta}'\widehat{Q}\widehat{\delta}
ight)^{2}}c$$

where

$$\begin{aligned} \hat{\delta} &= \hat{\beta}_{2} - \hat{\beta}_{1} \\ \hat{Q} &= \frac{1}{n} \sum_{t=1}^{n} \mathbf{x}_{t} \mathbf{x}_{t}' \\ \hat{\Omega} &= \frac{1}{n-k} \sum_{t=1}^{n} \mathbf{x}_{t} \mathbf{x}_{t}' \hat{e}_{t}^{2} + \frac{1}{n-k} \sum_{j=0}^{h-1} \sum_{t=1}^{T_{1}-j} \left(\mathbf{x}_{t} \mathbf{x}_{t+j}' \hat{e}_{t} \hat{e}_{t+j} + \mathbf{x}_{t+j} \mathbf{x}_{t}' \hat{e}_{t+j} \hat{e}_{t} \right) \end{aligned}$$

< 67 ▶

Confidence Intervals under Homoskedasticity

$$\widehat{T}_{1} \pm rac{n\widehat{\sigma}^{2}}{\left(\widehat{oldsymbol{eta}}_{2} - \widehat{oldsymbol{eta}}_{1}
ight)'(X'X)\left(\widehat{oldsymbol{eta}}_{2} - \widehat{oldsymbol{eta}}_{1}
ight)}c$$

-

3

Image: A matrix

Example

- Break for GDP Forecast
 - Point Estimate: 1980:4
 - Bai 90% Interval: 1979:2 1982:2
- Break for GDP Variance
 - Point Estimate: 1983:3
 - Bai 90% Interval: 1983:2 1983:4
 - Very tight

-

47 ▶

Confidence Intervals (Elliott-Mueller)

- Elliott-Mueller (JoE, 2007) argue that Bai's confidence intervals systematically undercover when breaks are small to moderate
- They recommend an alternative simple procedure
- For each breakdate T_1 for which the regression can be estimated
 - Calculate the regression

$$y_t = \widehat{\boldsymbol{\beta}}_0' \mathbf{z}_t + \widehat{\boldsymbol{\beta}}_1' \mathbf{x}_t \mathbf{1} (t \leq T_1) + \widehat{\boldsymbol{\beta}}_2' \mathbf{x}_t \mathbf{1} (t > T_1) + \hat{\mathbf{e}}_t$$

$$y_{t} = \widehat{\beta}_{0}'\mathbf{z}_{t} + \widehat{\beta}_{1}'\mathbf{x}_{t}\mathbf{1} (t \leq T_{1}) + \widehat{\beta}_{2}'\mathbf{x}_{t}\mathbf{1} (t > T_{1}) + \widehat{\mathbf{e}}_{t}$$

$$\widehat{\Omega}_{1} = \frac{1}{T_{1} - k} \left(\sum_{t=1}^{T_{1}} \mathbf{x}_{t}\mathbf{x}_{t}'\widehat{\mathbf{e}}_{t}^{2} + \sum_{j=0}^{h-1} \sum_{t=1}^{T_{1}-j} (\mathbf{x}_{t}\mathbf{x}_{t+j}'\widehat{\mathbf{e}}_{t}\widehat{\mathbf{e}}_{t+j} + \mathbf{x}_{t+j}\mathbf{x}_{t}'\widehat{\mathbf{e}}_{t+j}) \right)$$

$$\widehat{\Omega}_{2} = \frac{1}{n - T_{1} - k} \left(\sum_{t=T_{1}+1}^{n} \mathbf{x}_{t}\mathbf{x}_{t}'\widehat{\mathbf{e}}_{t}^{2} + \sum_{j=0}^{h-1} \sum_{t=T_{1}+1}^{n-j} (\mathbf{x}_{t}\mathbf{x}_{t+j}'\widehat{\mathbf{e}}_{t}\widehat{\mathbf{e}}_{t+j} + \mathbf{x}_{t+j}\mathbf{x}_{t}'\widehat{\mathbf{e}}_{t+j}) \right)$$

$$S_{j} = \sum_{t=1}^{j} \mathbf{x}_{t}\widehat{\mathbf{e}}_{t}$$

$$U(T_1) = \frac{1}{T_1^2} \sum_{j=1}^{I_1} S'_j \hat{\Omega}_1^{-1} S_j + \frac{1}{(n-T_1)^2} \sum_{j=T_1+1}^n S'_j \hat{\Omega}_2^{-1} S_j$$

Bruce Hansen (University of Wisconsin)

Theorem (Elliott-Muller)

 $U(T_1) \rightarrow_d \int_0^1 \overline{B}(s)'\overline{B}(s)ds$ where $\overline{B}(s)$ is a $2k \times 1$ Brownian bridge, $k = \dim(\mathbf{x}_t)$

This is the Cramer-vonMises distribution

- To form a confidence set for T_1 , find the set of T_1 for which $U(T_1)$ are less than the critical value
- The Elliott-Muller intervals can be much larger than Bai's
 - Unclear if they are perhaps too large

Critical Values for Confidence Intervals(Elliott-Muller Method)

Coverage

	99%	97.5%	95%	92.5%	90%	80%
k = 1	1.07	0.90	0.75	0.67	0.61	0.47

- 90% confidence region is set of values where $U(T_1)$ is less than critical value

GDP: Elliott-Muller U(t) Statistic for Confidence Interval

July 23-27, 2012 63 / 99

- 2

<ロ> (日) (日) (日) (日) (日)

Bruce Hansen (University of Wisconsin)

July 23-27, 2012 64 / 99

Example

Break for GDP Forecast

- Point Estimate: 1980:4
- Bai 90% Interval: 1979:2 1982:2
- Elliott-Muller: 1981:2 2011:2
- Break for GDP Variance
 - Point Estimate: 1983:3
 - Bai 90% Interval: 1983:2 1983:4
 - Elliott-Muller: 1980:4 1993:4
- Elliott-Muller intervals are much wider

Slope Estimators

• Estimate slopes from regression with estmate $\hat{\mathcal{T}}_1$

$$y_t = \widehat{\boldsymbol{\beta}}_0' \mathbf{z}_t + \widehat{\boldsymbol{\beta}}_1' \mathbf{x}_t \mathbf{1} (t \le T_1) + \widehat{\boldsymbol{\beta}}_2' \mathbf{x}_t \mathbf{1} (t > T_1) + \widehat{\mathbf{e}}_t(T_1)$$

- In the case of full structural change, this is the same as estimation on each sub-sample.
- Asymptotic Theory:
 - The sub-sample slope estimates are consistent for the true slopes
 - If there is a structural break, their asymptotic distributions are "conventional"
 - ★ You can treat the structural break as if known
 - Compute standard erros using conventional HAC formula

Example: Variance Estimates

- Pre 1983: $\hat{\sigma}_1^2 = 14.8~(2.3)$
- Post 193: $\hat{\sigma}_2^2 = 4.9 \ (1.0)$

Multiple Structural Breaks

• Breaks $T_1 < T_2$

$$y_t = \beta'_0 \mathbf{z}_t + \beta'_1 \mathbf{x}_t \mathbf{1} (t \le T_1) + \beta'_2 \mathbf{x}_t \mathbf{1} (T_1 < t \le T_2) + \beta'_3 \mathbf{x}_t \mathbf{1} (t > T_2) + e_t$$

- Testing/estimation: Two approaches
 - Joint testing/estimation
 - Sequential
- Major contributors: Jushan Bai, Pierre Perron

Joint Methods

Testing

- Test the null of constant parameters against the alternative of two (unknown) breaks
- Given T_1 , T_2 , construct Wald test for non-constancy
- Take the largest test over $T_1 < T_2$
- Asymptotic distribution a generalization of Andrews
- Estimation
 - The sum-of-squared errors is a function of (T_1, T_2)
 - The LS estimates (\hat{T}_1, \hat{T}_2) jointly minimize the SSE

Joint Methods - Computation

- For 2 breaks, these tests/estimates require $O(n^2)$ regressions
 - cumbersome but quite feasible
- For 3 breaks, naive estimation requires $O(n^3)$ regressions,
 - not feasible
- Bai-Perron developed efficient computer code which solves the problem of order $O(n^2)$ for arbitrary number of breaks
Sequential Method

- If the truth is two breaks, but you estimate a one-break model, the SSE will (asymptotically) have local minima at both breakdates
- Thus the LS breakdate estimator will consistently estimate one of the two breaks, e.g. \hat{T}_1 for T_1
- Given an estimated break, you can split the sample and test for breaks in each subsample
 - You can then find \hat{T}_2 for T_2
- Refinement estimator:
 - Split the entire sample at T₂
 - Now re-estimate the first break \hat{T}_1
 - The refined estimators are asymptotically efficient

Forecasting Focuses on Final Breakdate

- If you only want to find the last break
- First test for structural change on the full sample
- If it rejects, split the sample
- Test for structural change on the second half
- If it rejects, split again...

Forecasting After Breaks

イロト イヨト イヨト イヨト

Forecasting After Breaks

- There is no good theory about how to forecast in the presence of breaks
- There is a multitude of comflicting recommendations
- One important contribution:
 - Pesaran and Timmermann (JoE, 2007)
- They show that in a regression with a single break, the optimal window for estimation includes all of the observations after the break, and some of the observations before the break
- By including more observations you decrease variance at the cost of some bias
- They provide empirical rules for selecting sample sizes

Recommentation

- The simulations in Persaran-Timmermann suggest that there little gain for the complicated procedures
- The simple rule Split the sample at the estimated break seems to work as well as anything else
- My recommendation
 - ► Test for structural breaks using the Andrews or Bai/Perron tests
 - If there is evidence of a break, estimate its date using Bai's least-squares estimator
 - Calculate a confidence interval to assess accuracy (calculate both Bai and Elliott-Muller for robustness)
 - Split the sample at the break, use the post-break period for estimation
 - Use economic judgment to enhance statistical findings

DGP (Model C)

- $T_1 = 70$
- $\mu_1 = \mu_2 = 0.2$
- $\sigma_1^2 = 0.36$
- $\sigma_2^2 = 1.44$
- ho = 0.8

Assignment

- Take your favorite model
- Estimate the model allowing for one-time structure change in the mean
- Test the model for one-time structural change in the mean
- If appropriate, revise your forecasts
